The leach liquors pass through the ore to oxidise and dissolve the uranium minerals in situ. Depending on the type of leaching environment used the uranium will be complexed as either a uranyl sulphate, predominantly $UO_2(SO_4)_3 \cdot 4H_2O$, in acid leach conditions or a uranyl carbonate, predominantly $UO_2(CO_3)_3 \cdot 4H_2O$ in a carbonate leach system. This can then be precipitated with an alkali, e.g. as sodium or magnesium diuranate.

In Situ Leach Mining (ISL) of Uranium - World Nuclear ...

sandstone hosted uranium deposits amenable to ISL recovery are relatively widespread in the world. ISL technology recovers uranium using two alternative chemical leaching systems — acid and alkaline. Acid leach is the more widely employed and has historically produced a majority of the world's ISL production.

Manual of acid in situ leach uranium mining technology

In-situ leaching, also called in-situ recovery or solution mining, is a mining process used to recover minerals such as copper and uranium through boreholes drilled into a deposit, in situ. In situ leach works by artificially dissolving minerals occurring naturally in a solid state. For

recovery of material occurring naturally in solution, see: Brine mining. The process initially involves the drilling of holes into the ore deposit. Explosive or hydraulic fracturing may be used to create open pat

In situ leach (ISL) technology is an innovative and recently utilised mining alternative. It is recognized as having economic and environmental advantages when properly employed by knowledgeable specialists to extract uranium from suitable sandstone type deposits. This report brings together information from several technical disciplines that are an essential part of ISL technology.

Process for the in-situ leaching of uranium from a subterranean ore deposit comprising introducing into the deposit an aqueous lixiviant formulated from a dilute sulfuric acid solution which also contains carbon dioxide. The lixiviant has a pH within the range of 1.0-2.5. The lixiviant may also contain an alkali metal sulfate such as sodium ...

The leaching liquid used for in-situ leaching contains the leaching agent ammonium carbonate for example, or - particularly in Europe - sulfuric acid. This method can only be applied if the uranium deposit is located in porous rock, confined in impermeable rock layers.

In response to claims that acid in-situ leaching (ISL) mining of uranium in South Australia and disposal of wastes will contaminate groundwaters, the State Government requested the EPA to conduct...

Review of Environmental Impacts of the Acid In-situ Leach ...

Uranium acid mine drainage refers to acidic water released from a uranium mining site using processes like underground mining and in-situ leaching. Underground, the ores are not as reactive due to isolation from atmospheric oxygen and water. When uranium ores are mined, the ores are crushed into a powdery substance, thus increasing surface area to easily extract uranium.

Uranium acid mine drainage - Wikipedia

Uranium leaching is the process by which the uranium is extracted from the raw ore by reacting the material with acid or base. Fig. 2 shows a general process flow for the uranium extraction process. Prior to the leaching process, the ore is often given preliminary treatments that can include roasting and grinding.

Peninsula reduces alkaline operations at Lance in situ leach uranium mine in expectation of transition to acid leaching : On May 10, 2018, Peninsula Energy Limited advised that, in alignment with its planned transition to low pH operations at the Lance Projects, existing alkaline operations will be streamlined in order to preserve in-situ U₃O₈ pounds for future low pH extraction, and to reduce cash expenditure over the low pH permitting and transition period.

Column leaching test was carried out for uranium ore samples obtained from a uranium in-situ leaching (ISL) mining site using 2.45 bed volumes (BVs) of 0.255 M sulphuric acid to study the evolution of uranium concentration and its isotopic ²³⁴U/ ²³⁸U activity ratio in the pregnant leach solution.

EXECUTIVE SUMMARY In response to claims that acid in-situ leaching (ISL) mining of uranium in South Australia and disposal of wastes will contaminate groundwaters, the State Government requested the EPA to conduct an independent review of the environmental impacts of the mining process. CSIRO Land and Water was commissioned to conduct the Review.

Review of Environmental Impacts of the Acid In-situ Leach ...

First used in Wyoming in the 1950s, in-situ leaching (ISL) mining accounts for most uranium production in the United States. In situ leaching – what it is ISL involves injecting chemicals, called “lixivants” into an aquifer that contains a uranium ore body (i.e. deposit). The chemicals used are typically sulfuric acid or ammonium carbonate.
